

RMT AFORCE - International Workshop - Forest and Climate Change: adaptation initiatives and new management practices - Nancy, France

EVALUATING ADAPTATION OPTIONS TO COPE WITH DROUGHT EPISODES UNDER FUTURE CLIMATE

CONTRIBUTIONS FROM THE ON LINE WATER BALANCE CALCULATION TOOL BILJOU©

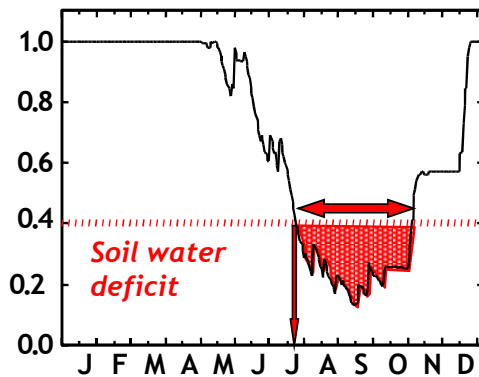

Nathalie BREDA, Vincent BADEAU, Damien MAURICE, André GRANIER
INRA, UMR1137 Forest Ecology and Ecophysiology
F-54280 Champenoux, France

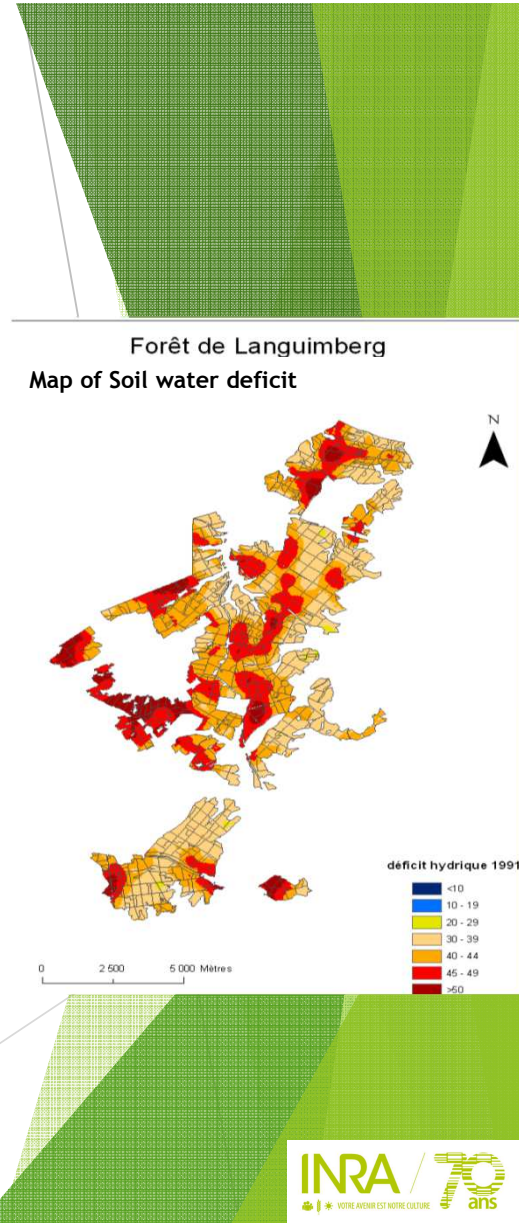

Climate services for drought events

- ▶ Climate services for impact and adaptation communities: consequences of past, present and future climate on water cycle, impacts on forest productivity, forest health ...
- ▶ Needs for drought events quantification: soil water deficit calculation by water balance and drought indices to compare years, stands, sites and contrasting climates

Relative extractable water

RMT AFORCE 2017- Bréda et al., INRA

Forest water balance model

INRA EEF Joint Research Unit Forest Ecology and Ecophysiology

Welcome Nath Breda | Log out

<https://appgeodb.nancy.inra.fr/biljou/>

- ▶ A water balance model firstly published in Ecological Modeling, by Granier et al. 1999
- ▶ Since 2010: dissemination to end-users in forest and water management, teachers and researchers from other communities
- ▶ One web site, two languages (French / English):
 - ▶ **E-learning web pages**: water balance, transpiration and its regulation, soil water reserve, phenology & LAI, meteorology, runoff, drought indicators, modelling, blue & green water; literature with downloading of pdf files -> *free access*
 - ▶ **An on line simulation tool**: to calculate by yourself the daily water balance of your favourite stands, using their soil and canopy parameters and a daily climatic data file; graphical interface, downloading facilities of data & pictures -> *account to be created and license acceptance*

more than 160 registered users, from 20 countries, more than 6950 runs

Dashboard of simulation results

Title and date	Specifications	Input files	Output files	Action
P14 Douglas (04 Aug 2016 11:04:29)	LAI: 6.0 Extraactable water: 153 mm Nb of years: 131 years	Site characteristics Meteorological data	Daily results Annual results	Display / Modify / Delete
P14 Douglas (04 Aug 2016 10:59:16)	LAI: 6.0 Extraactable water: 153 mm Nb of years: 21 years	Site characteristics Meteorological data	Daily results Annual results	Display / Modify / Delete

Graphs of simulation results

Aims of my talk: illustrate how to test the reduction of drought intensity by several adaptation options using Biljou© on line calculation tool

Case study: changes in drought events of a given Douglas-fir stand

- ▶ Stand characteristics:
 - ▶ Location: altitude, latitude, longitude
 - ▶ Soil properties to be described: soil depth, extractable soil water content, bulk density, fine roots distribution
 - ▶ Stand canopy assessment: sempervirent type and leaf area index

Runoff

Step 1: Quantifying past soil water deficits by retrospective water balance modelling

► Simulation condition:

- Observed Canopy type, Soil properties and leaf area index
- Observed daily climatic data file from a close weather station from National Meteorology Office or from a gridded modelled climatic data (in France: Safran) ; *recommendation: at least 10-30 years to describe inter-annual variability of the climate*

Past risk of drought induced decline: 15%

Step 2: Quantifying future soil water deficits using climatic scenarios

- ▶ Simulation condition:
 - ▶ Keep observed canopy type, soil properties and leaf area index
 - ▶ Change climate: daily future data from climatic scenario: rainfall, wind speed, vapour pressure deficit, radiation, temperature ; *recommendation: use several scenarios and methods of disaggregating climatic data from Global Climate Model to Regional Climate Model in order to assess climatic uncertainty*

**Future risk
of drought
induced
decline: 94%**

Step 3: testing incremental adaptation thanks to water saving silviculture (LAI reduction)

- ▶ Simulation condition:
 - ▶ Keep observed soil properties
 - ▶ Keep sempervirent canopy
 - ▶ Change leaf area index to a lower value (example: from 7 to 5)
 - ▶ Keep daily future climatic data from climatic scenario

Future risk of drought induced decline with incremental adaptation: 60%

Step 4: Combine soft and hard adaptation options: new Douglas-fir plantation on soil with higher extractable water with lowest LAI

- ▶ Simulation condition:
 - ▶ Keep observed sempervirent canopy and daily future climatic data from climatic scenario
 - ▶ Reduced observed LAI to a lowest value (i.e. from 7 to 4)
 - ▶ Change extractable water (i.e. from 100 mm to 150 mm)

Future risk of drought induced decline with relocation & LAI reduction: 49%

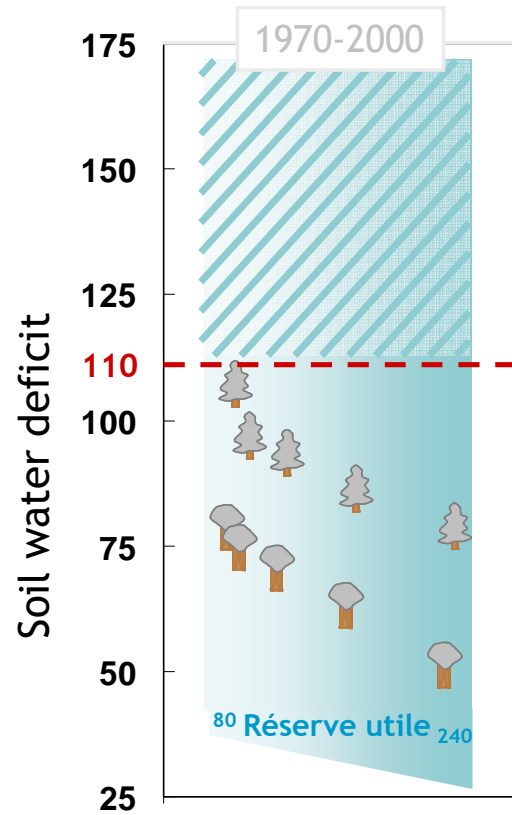

Step 4: Testing hard adaptation options: transformation from coniferous to deciduous species

- ▶ Simulation condition:
 - ▶ Keep observed soil properties
 - ▶ Change from sempervirent canopy to deciduous canopy
 - ▶ Keep daily future climatic data from climatic scenario

Future risk of
drought
induced
decline with
transformation:
37%

To sum up adaptations options to cope with future soil water deficit

To sum up adaptations options to cope with future soil water deficit

Adaptation options:

1. Limiter aux sols à forte RU
2. Couvert décidu sur même gamme de sol
3. Itinéraires à LAI réduit
4. Relocation

February 2017: 160 users for the calculation tool, 6910 runs
